Multimode optical cables are more expensive than single-mode cables

Overview

Various factors, including core diameter, cable length, and transceiver compatibility, influence the cost of fiber optic cabling.

Key Takeaways

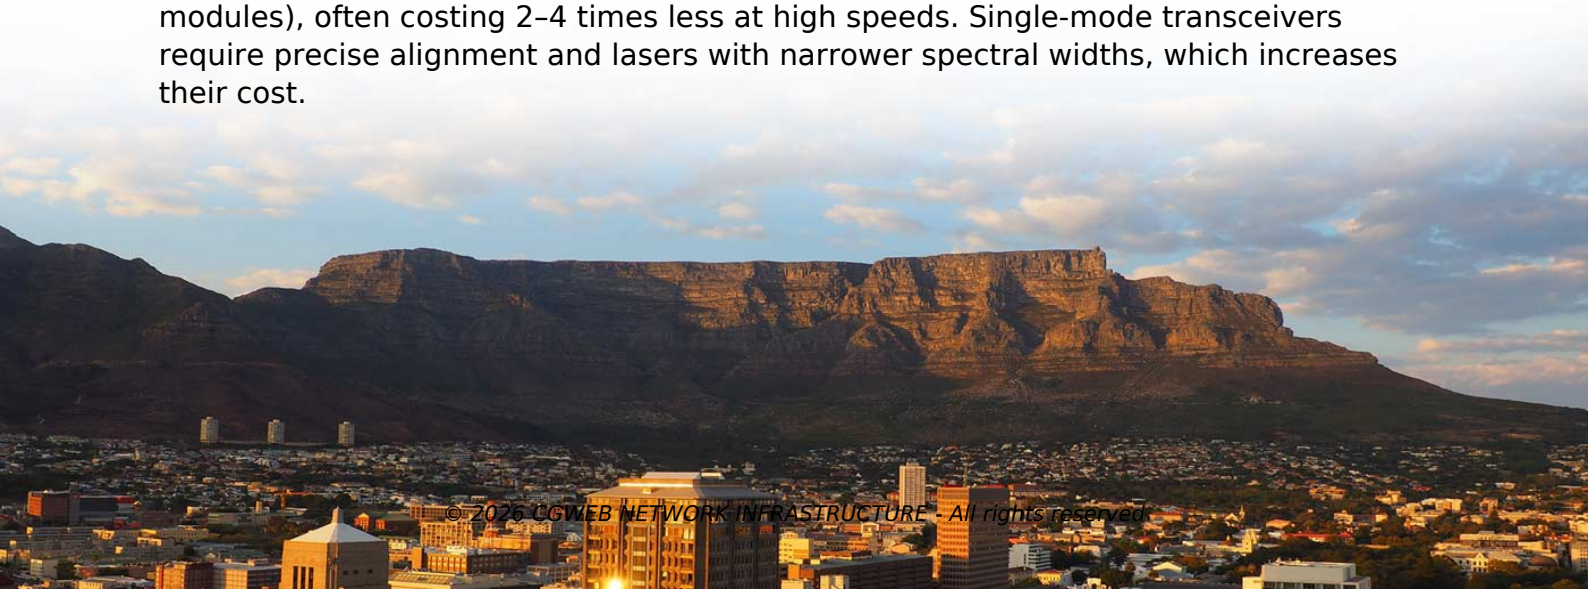

Multimode fiber cables are generally more expensive than single-mode cables, but multimode transceivers are cheaper than single-mode transceivers.

Cable Costs

Multimode fiber cables, especially OM4 and OM5 types, can be more expensive than single-mode fiber cables due to their larger core size and higher-grade materials used for high-speed short-distance applications. Single-mode fiber itself is usually cheaper to manufacture and install, particularly for long-distance or backbone networks.

Transceiver Costs

While multimode cables are more expensive, the transceivers for multimode fiber (e.g., SR modules) are significantly cheaper than single-mode transceivers (e.g., LR modules), often costing 2–4 times less at high speeds. Single-mode transceivers require precise alignment and lasers with narrower spectral widths, which increases their cost.

System and Installation Considerations

The overall system cost depends on both the fiber and transceiver expenses. For short-range applications like data centers, multimode fiber can be cost-effective due to lower transceiver costs and easier upgrades for 10G to 100G connections. However, for long-distance or future-proof networks, single-mode fiber is preferred because it supports higher bandwidth over longer distances and reduces the need for future cable upgrades.

Summary

Multimode fiber cables: Higher cable cost, lower transceiver cost, ideal for short distances and data centers. Single-mode fiber cables: Lower cable cost, higher transceiver cost, ideal for long distances, backbone networks, and future-proofing. In conclusion, while multimode cables themselves can be more expensive than single-mode cables, the total system cost often favors multimode for short-range applications due to cheaper transceivers and simpler upgrade paths.
