Should the relay protection tester be powered by AC or DC

Overview

The AC220V power supply is insured and enters the voltage adjusted by the small knob of the double carbon brush voltage regulator T1.

Key Takeaways

A relay protection tester should be powered by AC, typically 220V, and not by DC.

Input Power Requirements

Relay protection testers are designed to operate from an AC mains supply, commonly 220V single-phase AC, with proper grounding to ensure safety and device integrity. Connecting the tester to a DC supply or a higher-voltage AC source (e.g., 380V three-phase) is prohibited, as it can damage the instrument and compromise test accuracy. Proper grounding of the device is essential before testing to prevent electrical hazards and ensure reliable operation.

Output Capabilities

While the tester itself is powered by AC, it can generate both AC and DC voltage and current signals for testing relays. This allows simulation of various fault conditions, including overcurrent, short circuits, and voltage abnormalities, across both AC and DC relay types. The AC/DC outputs are internally generated by the tester's digital signal processing and amplifiers, independent of the AC input supply.

Safety and Operational Notes

Ensure the grounding wire is securely connected before powering the tester. Avoid overloading the voltage or current loops; the tester has built-in protections that cut off the amplifier if limits are exceeded. Follow the manufacturer's wiring instructions for connecting voltage, current, and binary inputs to prevent damage and ensure accurate relay testing.

Summary

Always power the relay protection tester with the specified AC supply.

The A

C input powers the device's internal electronics, which then generate precise AC and DC test signals for relay evaluation.

Using D

C as the input power is unsafe and can permanently damage the tester.
