Why do optical modules need a gearbox

Overview

A Gearbox is an internal module component that performs channel mapping and rate conversion between the module's electrical interface (host side) and its optical interface (fiber side). Operating at the physical layer of the OSI model, optical modules are core devices in optical. In these cases, a gearbox is used within the module to convert between the two rates. Particularly in the long-reach module market. The optical module serves as a crucial component in optical fiber communication systems, operating at the physical layer, which is the lowest layer in the OSI model. Among various optical module form factors, SFP (Small Form-Factor Pluggable). Optical transceivers (optical modules) are core photoelectric conversion components in fiber-optic communication, data centers, enterprise networks, and telecom transmission systems. Optical modules have a series of components inside, some of which have received attention from standards development organizations. In many cases, the baud rate of the optical interface does not equal the baud rate of the electrical interface. In these cases, a gearbox is used within the module to convert between the two rates. For example if the module supports 4 x 25 Gb/s electrical inputs and 2 wavelengths of 50 Gb/s optical inte
